Buffalo @ Minnesota

Ceiling-line QB stacks, priced with calibrated player probabilities × the walk-forward stack correlation (1.38×).

MODEL SCORE	MARKET	MINNESOTA QB	SIDE / TOTAL BET
BUF 27.8 – MIN 20.6	**BUF −3 · O/U 44.5**	**Carson Wentz** Kyler Murray Out	**None** no proven edge

THE PLAY

Slip 1 · Buffalo QB Stack

- **Josh Allen** over 249.5 passing yards (proj 225)
- **Khalil Shakir** over 49.5 receiving yards (proj 47)
- **DJ Moore** over 49.5 receiving yards (proj 43) — swap: Dalton Kincaid o49.5, same price

Fair **+830** Hit chance **10.8%** Bet only at **+830 or better**

OPTIONAL SLIPS

SLIP	LEGS	FAIR	HIT %	BET AT
2 · Shootout	Allen o249.5 pass yds · Wentz o224.5 pass yds · Shakir o49.5 rec yds	+1210	7.6%	+1210+
3 · Bring-back	Allen o249.5 pass yds · Shakir o49.5 rec yds · Jefferson o69.5 rec yds	+1275	7.3%	+1275+
4 · Minnesota stack	Wentz o224.5 pass yds · Jefferson o69.5 rec yds · Hockenson o49.5 rec yds	+1590	5.9%	+1590+
ATTD · fun money	James Cook · Josh Allen · Aaron Jones anytime TD	+890	10.1%	+900+

All QB slips share **Allen o249.5** (except Slip 4). If Buffalo runs the ball all night, they lose together. Slips 2–4 use stack types not separately validated in the full backtest; their boost is cut 10%.

BEFORE YOU BET

- Take a slip **only if your book pays at or above the "bet at" price**. Below it, the book has priced the correlation and the edge is gone.
- Stake **≤ 1% of bankroll** per slip. Confirm inactives ~90 minutes before kickoff.
- Log every slip with its price: `python -m research.bet_log add --ticket "MNF slip 1" --model-p 0.108 --price <odds> --stake <amt>`

WHY THE QB STACK

STRATEGY (ONE SLIP PER GAME)	SLIPS	HIT RATE	PREDICTED	ROI: BOOK PRICES LEGS SEPARATELY	ROI: BOOK PRICES CORRELATION
QB ceiling stack QB yds + 2 own WR/TE yds, lines just above projection	3,410	13.9%	13.3%	**+30.3%**	**−5.1%**
ATTD 2 + 1 split	3,676	5.3%	5.4%	**−12.6%**	**−11.1%**

Every prediction out-of-sample: player models, probability calibration and correlation boosts were fit only on earlier seasons. Legs on inactive players voided. No historical sportsbook prices exist, so returns are shown under two pricing assumptions (4.5% margin per leg).

WHAT WORKS

- The **QB is the hub**. Receivers only hit together when their QB has a big night (stack hits 1.38× its independent odds).
- Predictions are **calibrated**: 13.3% predicted vs 13.9% actual over 3,410 slips.
- Positive in **both halves**: +27% (2013–19), +33% (2020–26) under independent pricing.

WHAT DOESN'T

- **ATTD parlays**: no correlation edge once TD odds are calibrated (0.99×).
- **RB + own QB** stacks (0.98×) and receiver-only stacks (1.00×).
- **Game sides/totals**: model's edge vs closing lines vanished in 2025–26.

RISK PROFILE

Longest losing streak (QB stack)	**45 slips**
Worst drawdown (QB stack, 1-unit slips)	**−57 units**
Typical hit frequency	≈ 1 in 7 to 1 in 9

THE RULES

1. **One QB-hub stack per game**: QB passing yards + two of his own pass-catchers, each line just above projection.
2. **Price decides everything.** Bet only when the book pays at least our fair odds.
3. **≤ 1% of bankroll per slip** — sized to survive a 45-slip losing run.
4. **ATTD and lottery slips are fun money**, not edge plays.
5. **Log the offered price on every slip.** Whether books price the QB–receiver correlation is the single question that decides this strategy.

> **Bottom line:** Slip 1 is a good bet at +830 or better (confidence 7/10 in the method; ~1 in 9 to hit). Below +830, pass.
